Electronic Faucets
For Patient Care Applications
Electronic Faucets for Patient Care Applications (PCA)

In hospital rooms or patient rooms in nursing care facilities, Chicago Faucets offers a single source solution for the highest-quality faucets, affordable values, fast per case, and grab basis. We have developed and tested a line of electronic faucets specifically for patient care applications.

In addition to improved hygiene and added convenience, our faucets deliver:

- **Specified. Installed. Preferred.** Since 1901, Chicago Faucets has been the leader in commercial faucet quality and innovation. Today, you can find our products in leading healthcare facilities all across the country. The reason? We take the hassle out of selecting the right plumbing fixture for your application. This frees you to focus on your central mission: providing a safe, clean, comfortable environment. Here are just a few places where you can find our faucets:
  - Brigham and Women’s Hospital
  - Cedars Sinai Hospital
  - Cleveland Clinic
  - Children’s Hospital of Philadelphia
  - Kaiser Permanente
  - Massachusetts General Hospital
  - Mayo Clinic
  - Memorial Sloan-Kettering Cancer Center
  - Ronald Reagan Medical Center - UCLA
  - Shriners Children’s Hospital
  - St. Jude Heritage Medical Group
  - University of Iowa Medical Labs
  - University of Michigan Hospital
  - University of Pittsburgh Children’s Hospital
  - Veteran’s Administration Hospitals

- **ADA Compliant**
- **Next Day Shipping**

Our ECAST faucets are designed to meet new low lead initiatives and are manufactured with less than one-quarter of one percent (0.25%) total lead content by weighted average.

The Americans with Disabilities Act establishes accessibility guidelines for many products. Chicago Faucets offers an array of products that meet the requirements for ADA compliance.

Most Chicago Faucets products ship within 5-days. Products featured in our OPP program are available for shipment within 24 hours. Visit our website for a complete list of products.

The HyTronic® PCA

A new option for electronic faucets in patient care applications.

HyTronic® PCA is a new line of faucets designed specifically for patient care applications to complement your existing efforts. HyTronic® PCA faucets offer touch-free, dual-beam design that provides quick response time and the added safety of improved hygiene. Most of all, they limit the tested microbial contamination to a level statistically similar to standards set by a conventional manual faucet.

Water and the battle against bacteria within healthcare facilities.

From reinforcing hand-hygiene compliance to utilizing an arsenal of water treatment procedures, the campaign against the spread of bacteria is a primary concern among hospitals and long-term healthcare centers across the country. Water is an essential ingredient in the effort, ironically, water also contains small amounts of bacteria – making this battle even more challenging.

Hygiene, hand-washing, and electronic faucets.

For years, electronic faucets have been installed and have effectively improved hygiene, accessibility, and water efficiency. However, recent studies have raised concern that electronic faucets can elevate waterborne bacteria to a level that is higher than that found with conventional manual faucets. While most individuals are not at risk for infection by these bacteria, any increase is reason for concern in health care environments. Many health institutions are looking for ways to reduce exposure among individuals that might have a higher risk of contracting Legionnaires’ disease.

Emergency Backup Power System

Models with an emergency backup power system (EBPS) are now available! Our new Emergency Backup Power System (EBPS) allows you to install an AC-powered faucet with an integrated backup power system. EBPS gives you peace of mind, knowing that these electronic faucets will continue to deliver the necessary water during a power outage.

Hard-wire or Plug-in

You can connect AC powered faucets directly into your existing system with a choice of a multi-use hard-wire transformer or a convenient plug-in transformer.

Tested and validated by a nationally-recognized testing laboratory.

To validate our design assumptions, these products were extensively tested and monitored for both heterotrophic plate count (HPC) and Legionella bacteria. We utilized the test facilities at the University of Pittsburgh and had a culture and sample analysis performed by Special Pathogens Laboratory. SPL is a nationally-recognized analytical microbiology laboratory that specializes in the detection, control, and remediation of waterborne pathogens such as Legionella.

You will find a summary of the testing results at the back of this brochure. For the complete testing report, contact your sales representative or call Chicago Faucets customer service at 847-863-5000.

• Choice of power source – battery, hard-wire or plug-in
• Emergency Backup Power System (EBPS) available on select AC models
• Available with internal and user-adjustable mixers for temperature control
• Copper tube inlets

Research To Investigate Bacteria Growth in Electronic Faucets

Overview

Bacterial contamination of hot water systems is a common problem in large commercial facilities. Buildings such as hospitals, long-term health care centers, and hotels have large, complicated hot water distribution systems, and the growth of bacteria within these systems can cause both structural damage due to microbiologically-induced corrosion and human infection.

Legionella pneumophila are gram-negative bacteria which cause Legionnaires’ disease, a potentially fatal form of pneumonia. However, these bacteria are not at high risk of infection by these bacteria, but individual possession in a number of predisposing risk factors (age, immunocompromised, smoker, etc) at a greater risk of contracting Legionnaires’ disease should they be exposed to a contaminated source. Building hot water systems are sources of exposure to Legionella that have been linked to the cases of Legionnaires’ disease in several milieus [Colville et al. 1993, Goetz et al. 1998, Shands et al. 1985].

Heterotrophic plate count (HPC) measurements provide a general indicator of microbial water quality. They are used to determine the water treatment process effectiveness in HPC before treatment vs. HPC after treatment, as well as to indicate conditions which increase risk of microbial growth (e.g., high temperatures, lack of microbial sanitization, availability of nutrients, etc.) can persist in a given environment. Although most HPC are not pathogenic, the relative presence of microbial growth may be used as an indicator of the potential presence of pathogens (e.g., water with a large quantity of bacteria is more likely to have pathogens than water with very little bacteria).

Previous Research

In 2011, a study conducted by a leading healthcare institution indicated that sensor faucets are more susceptible to bacterial contamination than standard manual-spray faucets.

Scope Of And Reason For Additional Research

The study was based on evidence gathered from faucets installed in a real life situation and the comparison was limited to only one specific electronic faucet product and one reference manual faucet. A second study conducted by the University of Pittsburgh in 2012 was performed to determine whether these field observations could be reproduced under well-controlled laboratory conditions.

Research Objectives

The key objective of this laboratory study was to determine if electronic faucets are different from standard mechanical faucets in promoting Legionella growth, and if there exists a difference in any difference between these two faucet types in terms of the efficacy of standard decontamination practice (like chlorine addition) for Legionella evaluation.

Test setup and process

An automated faucet flushing process controller was installed on the test sensor faucet system to ensure consistent data collection without a flushing technician. The test system is left open for the duration of the investigation, and the passage of water through each faucet was controlled using interval timers. The opening and closing of these valves were programmed electronically to provide a constant, controlled water demand.

Legionella bacteria were prepared using a model hospital water distribution system supplied with municipal water. The bacteria were introduced into the system approximately one-week, and subsequent testing indicated Legionella concentrations in excess of 10,000 CFU/mL. A measured volume of this culture was fed into the system to achieve an initial concentration of 10,000 CFU/mL. The test was monitored for four weeks prior to a chlorination effort and two weeks post-chlorination. To decontaminate the system, a volume of 0.8 mL of 5% bleach was added to the faucet system flushing tank (a nick), and circulated through the system for 2 hours and 20 minutes. Following decontamination, system flushing was re-enabled and system operation resumed.

www.chicagofaucets.com
Results
In order to evaluate the significance of the observed differences between bacteria concentrations among different faucet groups, statistical analyses were performed using the collected data.

Legionella
It was found that each of the nine electronic faucets had an average concentration of Legionella bacteria that was comparable to the control faucet prior to chlorination. The mean difference of the faucet with the highest Legionella concentration prior to chlorination and the reference faucet was only 0.16 log CFU/mL.

Post-chlorination analyses also compared each sensor faucet to the control faucet, and the results indicate that five faucets demonstrated Legionella concentrations that were statistically equivalent to that of the control faucet. Two faucets, among them the one electronic faucet that was tested in the healthcare study, had Legionella concentrations that were more than 1.0 log higher than the control faucet.

HPC (Heterotrophic plate count)
Prior to chlorination, each of the electronic faucets harbored a population of total HPC which was equal to or greater than that of the control faucet. Five of the faucets were statistically indistinguishable from the control faucet. Four faucets demonstrated average pre-chlorination concentrations which were higher than those demonstrated by the reference faucet. The difference between the average concentration of the electronic faucet and the control faucet ranged from 0.03 log CFU/mL to 0.71 log CFU.

Post-chlorination comparisons of each of the sensor faucets with the control faucet indicate that one faucet maintained a population of HPC which was statistically equivalent to that of the control faucet. Two faucets, among them the one electronic faucet that was tested in the Johns Hopkins study, demonstrated microbial counts greater than 1.0 log higher than the control, while all remaining faucets demonstrated microbial concentrations that ranged from 0.22-0.37 log above that of the control.

Summary
This study was performed in a well-controlled lab environment by the University of Pittsburgh under guidance of Special Pathogens Laboratory, The Legionella Experts, and financed by Chicago Faucets. The objective was to determine if electronic faucets are any different from standard mechanical faucets in promoting Legionella growth and if there is any difference between these two faucet types in terms of the efficacy of standard disinfection practice.

Statistical analysis of experimental results obtained during the pre-chlorination phase revealed that there is no significant difference in the ability of sensor faucets to promote Legionella colonization when compared to a standard mechanical faucet.

Sensor faucets did harbor higher concentrations of HPC compared to mechanical faucets. The findings demonstrated that some faucets fostered higher microbial concentrations during regular usage. Conversely, other faucet types demonstrated the lowest microbial concentrations among sensor faucets.

Disinfection of the faucet system was performed five weeks into the trial.

Statistical analysis revealed that five electronic faucets did not demonstrate a statistically significant difference in Legionella concentration from the control faucet after chlorination. These results were confirmed using disinfection log reduction of HPC bacteria from pre- to post-chlorination.

Following disinfection, three electronic faucets continued to foster the highest microbial concentrations (HPC), while five other faucets were not statistically different when compared to the levels observed in a standard mechanical faucet.

Overall, it can be said that selected and modified electronic faucets perform as well as the mechanical reference faucet when it comes to promoting Legionella colonization and HPC. Based on the results of this study, Chicago Faucets offers a selection of four modified electronic faucet products with both AC and DC power options. For more information on these products consult a Chicago Faucets representative.

Credentials: Special Pathogens Laboratory provides the healthcare and water treatment industries, hotels, and commercial and industrial sectors a comprehensive solution for the prevention and control of Legionella. Founded by Dr. Janet Stout and Dr. Victor Yu, internationally recognized experts in Legionnaires’ disease.
Chicago Faucets, a member of the Geberit Group, is the leading brand of commercial faucets and fittings in the United States, offering a complete range of products for schools, laboratories, hospitals, office buildings, food service, airports, and sports facilities. Whatever your requirements may be, Chicago Faucets offers standard and made-to-order products that are designed to meet any commercial application.
